ABSTRACT

A server stores terminal information including an address of each terminal device belonging to a group constituted by a plurality of terminal devices. The server receives, from a terminal device belonging to the group, a distribution request including access information and distribution destination information. The server accesses the distribution information based on the access information, and receives the distribution information. The server specifies an address of a distribution destination terminal device based on the distribution destination information, and distributes the received distribution information to the destination terminal device.
